

ABSTRACT

In an adaptive array terminal, at least one of two antennas (ANT#1, ANT#2) is a movable antenna. A display unit (6) of the terminal displays reception levels of, or
5 level difference between, the two antennas. Thus, it becomes possible for a user to adjust an angle of the antenna such that reception levels of the two antennas come closer to the same level. Alternatively, a control unit (8) of the terminal automatically adjusts the antenna angle so that reception level difference between the two antennas becomes not higher than a prescribed value.
